

A few years ago, at the invitation of a friend, we went there to visit an edible oil factory. During the visit, the technical manager of the factory talked about a problem that had recently occurred. It was that the managers of the factory had changed some of their boilers and instead of several boilers, they had replaced two boilers with higher pressure and capacity. With this change, the produced oils of the factory started smelling like sludge, and some of the factory managers thought that this issue was related to the metal used in the boilers.
